# Overview

**Goal:** find a model which interrelate the forces applied on a model and the resulting deformations.

**Main idea:**

- Sample the continuous middle.
- Define a displacement field.
- Integrate over space the equations of continuous material

# Plan

## Overview:

- Sample the continuous middle:

Finite elements: with a 2D or 3D mesh.

Meshless deformations: with a point cloud.

- Define a displacement field.

Finite elements: interpolated in each cell.

Meshless deformations: weighted sum of a radial basis function.

- Integrate over space the equations of continuous material

For all methods, derive the physical equations from:

- partial derivatives of the displacements field
-

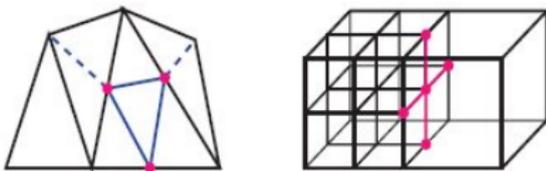

## Physical simulation:

	<b>Pros</b>	<b>Cons</b>
<b>Finite elements</b>	precision	mesh resolution
<b>Meshless deformations</b>	no topology => cutting, adaptivity	precision implementation
<b>mass-spring method</b>	implementation	precision edge mesh

## Principle:

The position of the skin (surface) is a linear combination of the bones (DOFs).

## Weighting:

Problem on large bend and twist deformations.

Solution: other weights.

Ex: arclength,  $1/d$ ,  $1/d^2$ , or as in [VGL, KunZhouetal.2005]

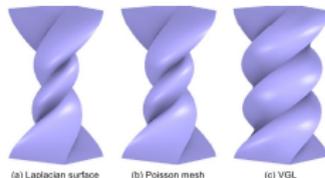

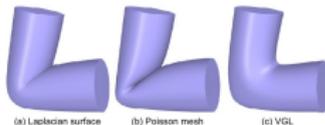

Figure 2: Large twist deformation.

## Kinematic primitive

New 12D DOF:

$$x = \left( \vec{t}, q, \vec{sh}, \vec{st} \right)^T$$

$$v = \left( \dot{\vec{t}}, \Omega, \dot{\vec{sh}}, \dot{\vec{st}} \right)^T$$

$$f = \left( \vec{f}_t, \vec{f}_r, \vec{f}_{sh}, \vec{f}_{st} \right)^T$$

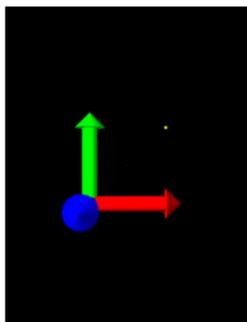

Figure: movie of shear effect

## Displacement field:

$$\vec{p}_0 = \vec{t}_0 + B_{1/0} * \vec{p}_1$$

with  $B_{1/0} = RE$ .

R is a rotation matrix  
 and E contains the shear and stretch components.

$$E = \begin{pmatrix} 1 + e_{xx} & e_{xy} & e_{zx} \\ e_{xy} & 1 + e_{yy} & e_{yz} \\ e_{zx} & e_{yz} & 1 + e_{zz} \end{pmatrix}$$

## Velocity of a point

$$\text{Coord: } \vec{p}_0 = \vec{t}_0 + B_{1/0} * \vec{p}_1$$

$$\text{Vel : } \dot{\vec{p}}_0 = \dot{\vec{t}}_0 + \dot{B}_{1/0} * \vec{p}_1$$

$$(\text{with } \dot{B}_{1/0} = \dot{R}E + R\dot{E})$$

## Displacement interpolation

$$\text{matrix: } J = \frac{du}{dx}$$

So,

$$\dot{\vec{p}}_0 = J(p) v_{DOF}$$

$$f_{DOF} = \sum J(p)^T \vec{f}_p$$

(according to virtual powers)

The mass matrix is used to compute accelerations.

According to Newton:  $f_{[12 \times 1]} = m_{[12 \times 12]} a_{[12 \times 1]}$

And according to the mechanic of continuous middle:  $M = \int \rho J J^T dv$

	$tr_{1 \times 3}$	$rot_{1 \times 3}$	$sh_{1 \times 3}$	$st_{1 \times 3}$
$tr_{3 \times 1}$	$M_{12 \times 12}$			
$rot_{3 \times 1}$				
$sh_{3 \times 1}$				
$st_{3 \times 1}$

We need a shear and stretch constraint to simulate the elasticity response on our deformable frames.

$$\dot{\vec{shear}} + = -k_{shear} * \vec{shear}$$
$$\dot{\vec{stretch}} + = -k_{stretch} * \vec{stretch}$$

We have linear deformations, but we want more !  
So, we create a spring to begin skinning with the DOFs.

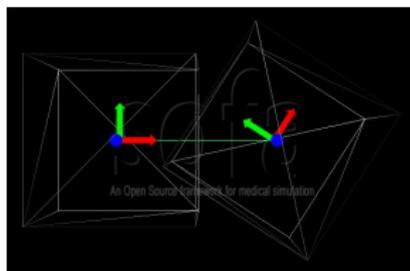

Figure: video of spring without damping

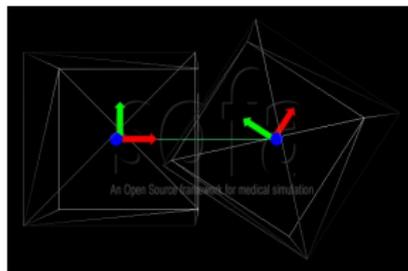

Figure: video of spring with damping

Now, we are able to do a linear combination between the DOFs.

Figure: demo using skinning

unrealistic deformation  $\Rightarrow$  We need local deformations.  
So, we create a contact manager.

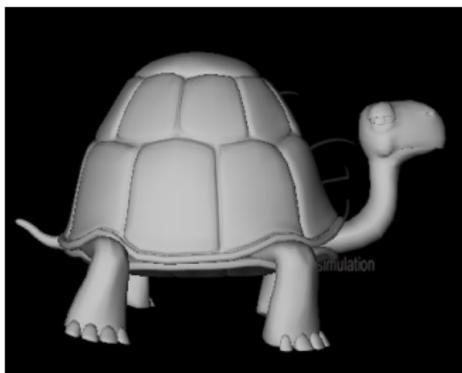

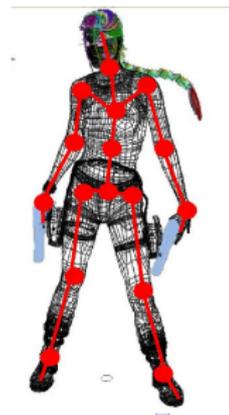

Figure: video of local deformations

- Finish the contact manager
- Animation applications
- Results physically exact
- Other functionalities

Automatically remove DOF  
Different influence radius

For medical simulation.

Compute the M, J and K matrices based on the mesh geometry or volumetric images.

According to the mechanic of continuous middle:

$$M = \int \rho J J^T dv$$

$$K = \int B^T C B dv$$

- Finish the contact manager
